Book royalties across three systems

Prepared for Berrett-Koehler Publishers. All example data below is fictional.

The problem

A mid-size publisher can run royalties in more than one system at once. Rates escalate, translations add contributors, subsidiary rights follow different terms, and each title still has to close on time.

Here is one fictional quarter for a small group of titles. The receipts are simple. The rules are not.

Item	Rule	Amount
Quarter receipts	All titles in the example	$184,600.00
Author A royalties	10% of receipts	$18,460.00
Author B royalties	10% on first $50,000, then 12.5%	$12,750.00
Translator share	3% of receipts	$5,538.00
Illustrator share	2% of receipts	$3,692.00
Co-publisher share	15% of receipts	$27,690.00
Publisher retained	Remainder	$116,470.00

When the rate schedule, the effective date, and the contributor list live in different systems, a correct total is hard to prove. Staff end up reconciling the systems instead of checking the rules.

> The burden is not the arithmetic. It is showing, title by title, which rule produced each amount.

The same example in RevRule

RevRule takes the same receipts and applies one recorded rule set per title. Inputs: the receipt event, the title, each contributor and role, the rate schedule, and the effective dates.

The engine calculates each entitlement and writes every step to a ledger that can be queried by title, participant, and period.

Participant	Rule applied	Amount owed
Author A	10% of receipts	$18,460.00
Author B	Escalating rate schedule	$12,750.00
Translator	3% of receipts	$5,538.00
Illustrator	2% of receipts	$3,692.00
Co-publisher	15% of receipts	$27,690.00
Publisher	Remainder	$116,470.00
Total	Matches receipts	$184,600.00

If a rate is corrected later, the correction is a new ledger entry. The original calculation stays visible, so the change can be explained instead of overwritten.

RevRule gives a publisher one place to define royalty rules and a record that shows how every amount was reached.
